1 Visualization

1. Google Collab:

<https://colab.research.google.com/drive/1jbuUiH5e5JZ5MhV6Jz9HU1yXbJoM6DN?usp=sharing>

We found that none of the features were strongly correlated. Since this was the case we had no cause to remove any of the features.

2. Visualizing

We made a bar plot to compare the blood glucose levels of those who had diabetes with those who did not have diabetes. As a result, we found that those who had diabetes (1), had much higher blood glucose levels on average, while those who did not have diabetes(0), had much lower average blood glucose levels (The blood glucose levels are scaled, hence the smaller numbers for blood glucose levels).

To better look at trends in seeing which groups have diabetes, we created a pie chart, which displays each group of BMI categories and the percentage of those which had diabetes patients fall into. We see that nearly 80 percent of people that have diabetes are either obese or overweight, with the rest being normal or underweight. We can accurately see a strong correlation with weight and predicting diabetes

3. we didn't do the machine learning part as we had tabular data.
